#### Abstract

The Tsakok test of fit is used to obtain an exact interval estimate of distributions and achieves exact two-sample tests, UMPU in a class of two-sided alternatives and not conditional on marginal totals. Comparisons and illustrations are made, an investigation into independent events is undertaken and an algorithm for computing the significance level of the Tsakok test of fit is given.

Keywords: UMPU, two-sample problem

## 1. INTRODUCTION

The chi-squared test by Pearson [1] has been extensively used to estimate distributions and in contingency tables, but as Kendall and Stuart [2, p. 453] pointed out, it cannot be expected to be unbiased in general; other than being inexact and uses distributions conditional on marginal totals. These are overcome by the Tsakok [3] test of fit, since it is exact (with test sizes easily calculated directly from the multinomial distribution) and Uniformly Most Powerful Unbiased (UMPU) in a class of two-sided alternatives.

The Tsakok test of fit enables an exact UMPU twosample test, using distributions which are not conditional on marginal totals, and so compares favorably to other alternatives. It is a frequent practical problem, as the example illustrates, and solves the two-sample problem; considered by Euler (Kendall and Stuart [2], p 512).

## 2. ESTIMATING DISTRIBUTIONS

The Tsakok [3] test of fit has been shown to exist as specified: Let independent observations be made on a random vector X in $\mathbf{R}^{\mathrm{N}}$, with unknown, possibly continuous, distribution F . The range along which X varies is partitioned into k mutually exclusive prespecified classes $i=1, \ldots k$. For each class $i$, let $n_{i}$ be the number of observations falling into $i$, and $p_{i}$ be the probability of an observation occurring in class i. So $\sum_{i=1}^{k} \mathrm{p}_{\mathrm{i}}=1$. Let $\sum_{i=1}^{k} \mathrm{n}_{\mathrm{i}}=\mathrm{n}$. If $\mathrm{F}=\mathrm{F}_{0}$ for some distribution $\mathrm{F}_{0}$, then $\mathrm{p}_{\mathrm{i}}=\mathrm{p}_{0 \mathrm{i}} \forall$ i. $\mathrm{n}_{\mathrm{i}}=\mathrm{x}_{\mathrm{i}}$ from the data. So $x_{i}$ is a particular value of $n_{i}$.

To test $\mathrm{H}_{0}: \mathrm{p}_{\mathrm{i}}=\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k})$ against $\mathrm{H}_{1}: \mathrm{p}_{\mathrm{i}} \neq \mathrm{p}_{0 \mathrm{i}}$ for at least one i ; the test $f$ is, in the non-randomized case:
$f=1$ when $\mathrm{n}_{\mathrm{i}} \leq \mathrm{c}_{\mathrm{i} 1}$ or $\mathrm{n}_{\mathrm{i}} \geq \mathrm{c}_{\mathrm{i} 2}$ given $\mathrm{n}_{\mathrm{j}} \forall \mathrm{j} \neq \mathrm{i}, \mathrm{k}$ for at least one $\mathrm{i}=1, \ldots \mathrm{k}-1$;

$$
f=0 \text { otherwise }
$$

where the integer interval acceptance region $\left[\left(\mathrm{c}_{\mathrm{i} 1}, \mathrm{c}_{\mathrm{i} 2}\right) \mid \mathrm{n}_{\mathrm{j}}\right.$ $\forall \mathrm{j} \neq \mathrm{i}, \mathrm{k}]$ for which $0 \leq \mathrm{c}_{\mathrm{i} 1} \leq \mathrm{n}, 0 \leq \mathrm{c}_{\mathrm{i} 2} \leq \mathrm{n}$ is subject to

$$
\begin{align*}
& \mathrm{E}\left(f \mid \mathrm{H}_{0}\right)=\alpha \quad 0<\alpha<1  \tag{1}\\
& \mathrm{E}\left(\mathrm{n} f \mid \mathrm{H}_{0}\right)=\alpha \mathrm{E}\left(\mathrm{n}_{\mathrm{i}} \mid \mathrm{H}_{0}\right) \tag{2}
\end{align*}
$$

for $\mathrm{i}=1, \ldots \mathrm{k}-1$, at the test size $\alpha$. This test is UMPU against alternatives under $\mathrm{H}_{1}$ for which $\mathrm{p}_{\mathrm{i}}$ differs from $\mathrm{p}_{0 \mathrm{i}}$ for only one $\mathrm{i}(\mathrm{i}=1, \ldots \mathrm{k}-1)$.

Lemma 2.1. Properties of unbiasedness condition (2) given n and $\mathrm{n}_{\mathrm{j}} \forall \mathrm{j} \neq \mathrm{i}, \mathrm{k}$.
(i) The Tsakok test $f$ satisfies the unbiasedness condition when $\mathrm{c}_{\mathrm{i} 1}=\mathrm{np}_{0 \mathrm{i}}-\mathrm{d}_{\mathrm{i} 1}, \mathrm{c}_{\mathrm{i} 2}=\mathrm{np}_{0 \mathrm{i}}+\mathrm{d}_{\mathrm{i} 2}$, for some integers $\mathrm{d}_{\mathrm{i} 1}$, $\mathrm{d}_{\mathrm{i} 2}>0$ for which $\mathrm{n} \geq \mathrm{c}_{\mathrm{i} 1} \geq 0$ and $0 \leq \mathrm{c}_{\mathrm{i} 2} \leq \mathrm{n}$.
(ii) The unbiasedness condition for $f$ is satisfied iff there exists real functions $\mathrm{I}_{1}\left(\mathrm{~d}_{\mathrm{i} 1}\right), \mathrm{I}_{2}\left(\mathrm{~d}_{\mathrm{i} 2}\right)$ such that $\mathrm{E}\left(\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f\right.$ $\left.\mid \mathrm{H}_{0}\right)=\mathrm{I}_{2}\left(\mathrm{~d}_{\mathrm{i} 2}\right)-\mathrm{I}_{1}\left(\mathrm{~d}_{\mathrm{i} 1}\right)=0 . \mathrm{I}_{1}\left(\mathrm{~d}_{\mathrm{i} 1}\right) \geq 0, \mathrm{I}_{2}\left(\mathrm{di}_{2}\right) \geq 0$ and vary monotonically with $\mathrm{d}_{\mathrm{i} 1}, \mathrm{~d}_{\mathrm{i} 2}$ respectively, with $\mathrm{d}_{\mathrm{i} 1}, \mathrm{~d}_{\mathrm{i} 2}$ sufficiently large to prevent them from satisfying the conditions:

$$
\mathrm{d}_{\mathrm{i}}=\mathrm{d}_{\mathrm{i} 1} \text { or } \mathrm{d}_{\mathrm{i} 2} \text { for which } \mathrm{n}_{\mathrm{i}}=\mathrm{np}_{\mathrm{i}}+\mathrm{d}_{\mathrm{i}} \in \mathbf{Z} \text {, the set of }
$$ integers $(\mathrm{i}=1, \ldots \mathrm{k}), \sum_{i=1}^{k} \mathrm{~d}_{\mathrm{i}}=0,\left|\mathrm{~d}_{\mathrm{r}}-\mathrm{d}_{\mathrm{s}}\right|<1$, and $p_{s}\left(n p_{r}+d_{r}\right) \neq p_{r}\left(n p_{s}+d_{s}+1\right)$ for any distinct pair of classes $r$ and $s$.

(iii) There exists $\alpha$ such that integers $\mathrm{d}_{\mathrm{ij}}=\mathrm{m}_{\mathrm{ij}}$ and $\mathrm{m}_{\mathrm{il}}<$ $\mathrm{np}_{0 \mathrm{i}}, \mathrm{m}_{\mathrm{ij}} / \mathrm{n}<1(\mathrm{j}=1,2)$ for which $\mathrm{c}_{\mathrm{i} 1}=\mathrm{np}_{0 \mathrm{i}}-\mathrm{m}_{\mathrm{i} 1}, \mathrm{c}_{\mathrm{i} 2}=$ $n p_{0 i}+m_{i 2}$ for any choice of $p_{0 i}(i=1, \ldots k-1)$ with $\sum_{i=1}^{k} \mathrm{p}_{0 \mathrm{i}}=1$.

Proof. (i) and (ii). Putting $\mathrm{c}_{\mathrm{i} 1}=\mathrm{np}_{0 \mathrm{i}}-\mathrm{d}_{\mathrm{i} 1}, \mathrm{c}_{\mathrm{i} 2}=\mathrm{np}_{0 \mathrm{i}}+$ $d_{i 2}$ for some integers $d_{i 1}, d_{i 2}>0$, given $n_{j} \forall j \neq i$, k; the $\mathrm{d}_{\mathrm{i} 1}, \mathrm{~d}_{\mathrm{i} 2}$ are chosen to satisfy the unbiasedness condition as follows:
$\mathrm{E}\left(\mathrm{n}_{\mathrm{i}} f \mid \mathrm{H}_{0}\right)=\mathrm{E}\left(\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f \mid \mathrm{H}_{0}\right)+\mathrm{np}_{0 \mathrm{i}} \mathrm{E}\left(f \mid \mathrm{H}_{0}\right)=$ $\mathrm{np}_{0 \mathrm{i}} \mathrm{E}\left(f \mid \mathrm{H}_{0}\right)=\alpha \mathrm{E}\left(\mathrm{n}_{\mathrm{i}} \mid \mathrm{H}_{0}\right)$
iff $\mathrm{E}\left(\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f \mid \mathrm{H}_{0}\right)=0$, given that $\mathrm{np}_{0 \mathrm{i}} \mathrm{E}\left(f \mid \mathrm{H}_{0}\right)$ is bounded, with n fixed. With randomization constants $\gamma_{1}$, $\gamma_{2}$, this can be expressed as:

$$
\mathrm{E}\left(\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f \mid \mathrm{H}_{0}\right)=\mathrm{I}_{2}\left(\mathrm{~d}_{\mathrm{i} 2}\right)-\mathrm{I}_{1}\left(\mathrm{~d}_{\mathrm{i} 1}\right)=0
$$

where, if $\mathrm{P}_{\mathrm{i}}=\mathrm{P}\left(\mathrm{n}_{\mathrm{i}} \leq \mathrm{x} \mid \mathrm{H}_{0}, \mathrm{n}_{\mathrm{j}} \forall \mathrm{j} \neq \mathrm{i}, \mathrm{k}\right)$ for some real $x \geq 0$, and $0 \leq \gamma_{1} \leq 1,0 \leq \gamma_{2} \leq 1$;
$\mathrm{I}_{2}=\int \mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}} \mathrm{dP}_{\mathrm{i}}+\gamma_{1} \mathrm{~d}_{\mathrm{i} 2} \mathrm{P}\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}=\mathrm{d}_{\mathrm{i} 2} \mid \mathrm{H}_{0}, \mathrm{n}_{\mathrm{j}} \forall \mathrm{j} \neq \mathrm{i}, \mathrm{k}\right)$
$\left(\mathrm{n}_{\mathrm{i}}: \mathrm{np}_{0 \mathrm{i}}+\mathrm{d}_{\mathrm{i} 2}<\mathrm{n}_{\mathrm{i}} \leq \mathrm{n}-\sum_{(\mathrm{j} \text { : for all } \mathrm{j} \neq \mathrm{i}, \mathrm{k})} \mathrm{n}_{\mathrm{j}}\right)$
$\mathrm{I}_{1}=\int \mathrm{np}_{0 \mathrm{i}}-\mathrm{n}_{\mathrm{i}} \mathrm{dP}_{\mathrm{i}}+\gamma_{2} \mathrm{~d}_{\mathrm{i} 1} \mathrm{P}\left(\mathrm{np}_{0 \mathrm{i}}-\mathrm{n}_{\mathrm{i}}=\mathrm{d}_{\mathrm{i} 1} \mid \mathrm{H}_{0}, \mathrm{n}_{\mathrm{j}} \forall \mathrm{j} \neq \mathrm{i}, \mathrm{k}\right)$
$\left(\mathrm{n}_{\mathrm{i}}: \mathrm{np}_{0 \mathrm{i}}{ }^{-} \mathrm{d}_{\mathrm{i} 1}>\mathrm{n}_{\mathrm{i}} \geq 0\right)$
By inspection, $\mathrm{I}_{1}$ and $\mathrm{I}_{2}$ are both positive and vary monotonically with $\mathrm{d}_{\mathrm{i} 1}, \mathrm{~d}_{\mathrm{i} 2}$ respectively, where $\mathrm{d}_{\mathrm{i} 1}, \mathrm{~d}_{\mathrm{i} 2}>0$, when $\quad d_{i 1}, d_{i 2}$ are sufficiently large so that $\left(\mathrm{np}_{0 \mathrm{i}}{ }^{-} \mathrm{d}_{\mathrm{i} 1}\right.$, $\left.\mathrm{np}_{0 \mathrm{i}}+\mathrm{d}_{\mathrm{i} 2}\right)$ contains the maximal value of Prob. $\left(\mathrm{n}_{1}, \ldots \mathrm{n}_{\mathrm{k}} \mid \mathrm{H}_{0}\right)$, given i. According to Tsakok [3], these conditions are: integer values of $d_{i}=d_{i 1}$ or $d_{i 2}$ for which $n_{i}=n p_{i}+d_{i} \in \mathbf{Z}$
( $\mathrm{i}=1, \ldots \mathrm{k}$ ), where $\sum_{i=1}^{k} \mathrm{~d}_{\mathrm{i}}=0,\left|\mathrm{~d}_{\mathrm{r}}-\mathrm{d}_{\mathrm{s}}\right|<1$, and $\mathrm{p}_{\mathrm{s}}$ $\left(n p_{r}+d_{r}\right) \neq p_{r}\left(n p_{s}+d_{s}+1\right)$ for any distinct pair of classes $r$ and $s$.
(iii) Since $1>\alpha>0, c_{i 1}=n p_{0 i}-d_{i 1}$ and $c_{i 2}=n p_{0 i}+d_{i 2}$ given $\mathrm{n}_{\mathrm{j}} \forall \mathrm{j} \neq \mathrm{i}$, k , this means $0 \leq \mathrm{c}_{\mathrm{i} 1} \leq \mathrm{np}_{0 \mathrm{i}}$ and $\mathrm{np}_{0 \mathrm{i}} \leq \mathrm{c}_{\mathrm{i} 2} \leq$ n , as $\mathrm{c}_{\mathrm{i} 1} \geq 0$ and $\mathrm{c}_{\mathrm{i} 2} \leq \mathrm{n}$; being possible values of $\mathrm{n}_{\mathrm{i}}$ to satisfy (1). Setting $\mathrm{d}_{\mathrm{i} 1}=\mathrm{m}_{\mathrm{i} 1}$ and $\mathrm{d}_{\mathrm{i} 2}=\mathrm{m}_{\mathrm{i} 2}$ when $\mathrm{c}_{\mathrm{i} 1}=\mathrm{np}_{0 \mathrm{i}}$ - $\mathrm{d}_{\mathrm{i} 1}$ and $\mathrm{c}_{\mathrm{i} 2}=\mathrm{np}_{0 \mathrm{i}}+\mathrm{d}_{\mathrm{i} 2}$, for some integers $\mathrm{m}_{\mathrm{i} 1}$ and $\mathrm{m}_{\mathrm{i} 2}, \alpha$ is then chosen to be sufficiently large so that $\mathrm{m}_{\mathrm{i} 1}<\mathrm{np}_{0 \mathrm{i}}$, $\mathrm{m}_{\mathrm{i} 1} / \mathrm{n}<1$ and $\mathrm{m}_{\mathrm{i} 2} / \mathrm{n}<1(\mathrm{i}=1, \ldots \mathrm{k}-1)$, for any choice of $\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k})$
$\uparrow$
Definition 2.2. A value of $\mathrm{p}_{\mathrm{i}}$ is said to be acceptable by a test $f$ at the test size $\alpha$ if it can be accepted to be a value of $\mathrm{p}_{\mathrm{i}}$ if tested using the test $f$ at the test size $\alpha$.

Definition 2.3. A test size $\alpha \in(0,1)$ which satisfies the conditions of Lemma 2.1 is said to be sufficiently large.

Theorem 2.4. For sufficiently large test size $\alpha$ given n :
(i) There exists an interval estimate ( $\mathrm{p}_{\mathrm{l}}, \mathrm{p}_{\mathrm{ui}}$ ) of $\mathrm{p}_{\mathrm{i}}(\mathrm{i}=1$, ... $\mathrm{k}-1$ ) formed from acceptable values of $\mathrm{p}_{\mathrm{i}}$ using the test $f$.
(ii) There exists a sequence of values $p_{\text {uilr }}$ and $p_{u i 2 r}$ such that $p_{u i l r} \geq p_{u i} \geq p_{u i 2 r}$ with $p_{u i l r} \rightarrow p_{u i}$ and $p_{u i 2 r} \rightarrow p_{u i}$ as $r$ $\rightarrow \infty(\mathrm{i}=1, \ldots \mathrm{k}-1)$. Similarly, there exists a sequence of values $p_{\text {liir }}$ and $p_{\text {li2r }}$ such that $p_{\text {liir }} \geq p_{\text {li }} \geq p_{\text {li2r }}$ with $p_{\text {lilr }} \rightarrow p_{\text {li }}$ and $\mathrm{p}_{\mathrm{li} 2 \mathrm{r}} \rightarrow \mathrm{p}_{\mathrm{li}}$ as $\mathrm{r} \rightarrow \infty(\mathrm{i}=1, \ldots \mathrm{k}-1)$.

Proof. (i) In the test $f$, the unbiasedness condition is met by choosing $\mathrm{d}_{\mathrm{i} 1} / \mathrm{d}_{\mathrm{i} 2}$ as follows: If $\mathrm{d}_{\mathrm{i} 1}$ is such that $\mathrm{I}_{1}\left(\mathrm{~d}_{\mathrm{i} 1}\right)$ is too large when compared to $\mathrm{I}_{2}\left(\mathrm{~d}_{\mathrm{i} 2}\right), \mathrm{E}\left(\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f \mid \mathrm{H}_{0}\right)$ $<0$, while if $\mathrm{d}_{\mathrm{i} 2}$ is such that $\mathrm{I}_{2}\left(\mathrm{~d}_{\mathrm{i} 2}\right)$ is too large in relation to $\mathrm{I}_{1}\left(\mathrm{~d}_{\mathrm{i} 1}\right), \mathrm{E}\left(\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f \mid \mathrm{H}_{0}\right)>0$. Thus as $\mathrm{E}\left(\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f\right.$ $\left.\mid \mathrm{H}_{0}\right)$ varies with $\mathrm{d}_{\mathrm{i} 1}, \mathrm{~d}_{\mathrm{i} 2}\left(\mathrm{~d}_{\mathrm{i} 1}, \mathrm{~d}_{\mathrm{i} 2}>0\right)$; there is a value of $\mathrm{d}_{\mathrm{i} 1} / \mathrm{d}_{\mathrm{i} 2}$ for which $\left.\mathrm{E}\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f \mid \mathrm{H}_{0}\right)=0$, possibly using randomization constants $\gamma_{1}, \gamma_{2}$. The actual values of $\mathrm{d}_{\mathrm{i} 1}, \mathrm{~d}_{\mathrm{i} 2}$ can then be chosen to satisfy the required test size. $\alpha$ must moreover be sufficiently large with $\mathrm{P}\left(\mathrm{n}_{\mathrm{i}}>\mathrm{np}_{0 \mathrm{i}}+\mathrm{d}_{\mathrm{i} 1} \mid \mathrm{H}_{0}, \mathrm{n}_{\mathrm{j}}\right.$ $\forall \mathrm{j} \neq \mathrm{i}, \mathrm{k})>0$ and $\mathrm{P}\left(\mathrm{n}_{\mathrm{i}}<\mathrm{np}_{0 \mathrm{i}}-\mathrm{d}_{\mathrm{i} 1} \mid \mathrm{H}_{0}, \mathrm{n}_{\mathrm{j}} \forall \mathrm{j} \neq \mathrm{i}, \mathrm{k}\right)>0$, since otherwise it would not be a two-sided test.
$\mathrm{d}_{\mathrm{i} 1}$ and $\mathrm{d}_{\mathrm{i} 2}(\mathrm{i}=1, \ldots \mathrm{k}-1)$ thus chosen meets the unbiasedness requirement for any $p_{0 i} \in(0,1)$, and are bounded above by some integers $\mathrm{m}_{\mathrm{i} 1}, \mathrm{~m}_{\mathrm{i} 2}$ respectively such that $m_{i j} / n<1(j=1,2)$, for sufficiently large $\alpha$.

Suppose changing $\mathrm{p}_{0 \mathrm{i}}$ to $\mathrm{p}_{0 \mathrm{i}}+\Delta \mathrm{p}_{0 \mathrm{i},}$ for some real $\Delta \mathrm{p}_{0 \mathrm{i}}>$ 0 , causes $\mathrm{E}\left(\left(\mathrm{n}_{\mathrm{i}}-\mathrm{np}_{0 \mathrm{i}}\right) f \mid \mathrm{H}_{0}\right) \neq 0$. Unbiasedness can then be restored by varying $\mathrm{d}_{\mathrm{i} 1} / \mathrm{d}_{\mathrm{i} 2}$, at the given constant test size. If $p_{0 i}=x_{i} / n$ initially, successive increments of $\Delta p_{0 i}$ may then require corresponding adjustments in $\mathrm{d}_{\mathrm{i} 1} / \mathrm{d}_{\mathrm{i} 2}$ at the required test size. This process can continue until $x_{i} / n$ does not belong to the interval ( $\mathrm{x}_{\mathrm{i}} / \mathrm{n}+\delta-\mathrm{m}_{\mathrm{i} 1} / \mathrm{n}, \mathrm{x}_{\mathrm{i}} / \mathrm{n}+\delta$ $+\mathrm{m}_{\mathrm{i} 2} / \mathrm{n}$ ); where $\mathrm{p}_{0 \mathrm{i}}=\mathrm{x}_{\mathrm{i}} / \mathrm{n}+\delta$, for some real $\delta$ obtained from increases of $\Delta \mathrm{p}_{0 \mathrm{i}}$ such that $\mathrm{x}_{\mathrm{i}} / \mathrm{n}+\delta>\mathrm{m}_{\mathrm{i} 1} / \mathrm{n}$. Similar considerations apply if variations $\mathrm{p}_{0 \mathrm{i}}-\Delta \mathrm{p}_{0 \mathrm{i}}$ are made, where $\Delta \mathrm{p}_{0 \mathrm{i}}>0$, starting from when $\mathrm{p}_{0 \mathrm{i}}=\mathrm{x}_{\mathrm{i}} / \mathrm{n}$. This shows that, for a given sample of observations, values of $\mathrm{p}_{0 \mathrm{i}}$ which may be accepted for $p_{i}$ vary within an interval for each i , using $f$ given sufficiently large $\alpha$ and $\mathrm{m}_{\mathrm{i} 1}, \mathrm{~m}_{\mathrm{i} 2}(\mathrm{i}=$ $1, \ldots \mathrm{k}-1$ ).
(ii) Let $\left(\mathrm{p}_{\mathrm{l},}, \mathrm{p}_{\mathrm{ui}}\right)$ be an interval along which acceptable values of $\mathrm{p}_{\mathrm{i}}$ are allowed to vary at a sufficiently large $\alpha$, with $f$. An iterative procedure is now used to determine ( $\mathrm{p}_{\mathrm{li},} \mathrm{p}_{\mathrm{ui}}$ ). Using an acceptance region of $\mathrm{p}_{\mathrm{i}}$ (using $f$ ) as an initial estimate of $\left(\mathrm{p}_{\mathrm{l}}, \mathrm{p}_{\mathrm{ui}}\right)$, an upper and lower bound is obtained for $\mathrm{p}_{\mathrm{li}}$ and $\mathrm{p}_{\mathrm{ui}}$ by trial and improvement.

Let the upper and lower bound of $\mathrm{p}_{\mathrm{ui}}$ be $\mathrm{p}_{\text {uiUr }}$ and $\mathrm{p}_{\text {uiLr }}$ respectively at the $\mathrm{r}^{\text {th }}$ iteration, with $f$. Denote the corresponding acceptance regions for $\mathrm{p}_{\text {uiUr }}$ and $\mathrm{p}_{\text {uiLr }}$ by $\left(c_{i 1}(U, r), c_{i 2}(U, r)\right)$ and $\left(c_{i 1}(L, r), c_{i 2}(L, r)\right)$ respectively.

With $\left(\mathrm{c}_{\mathrm{i} 1}, \mathrm{c}_{\mathrm{i} 2}\right)$ as above with $\mathrm{p}_{0 \mathrm{i}}$ varying with the $\mathrm{r}^{\text {th }}$ iteration, an upper bound of $\mathrm{p}_{\mathrm{ui}}$ is a hypothetical value of $p_{u i}$ which is rejected, with $n_{i}<c_{i 1}(U, r)$ for rejection of $p_{\text {uiUr. }}$ A lower bound of $p_{u i}$ is a hypothetical value of $\mathrm{p}_{\mathrm{ui}}$ which is accepted, with $\left(c_{i 1}(L, r)<n_{i}<c_{i 2}(L, r)\right)$ for acceptance of $\mathrm{p}_{\text {uiLr }}$. The inequality $\mathrm{p}_{\mathrm{uiUr}} \geq \mathrm{p}_{\mathrm{ui}} \geq \mathrm{p}_{\text {uiLr }}$ is now constructed as follows:

An initial test is made using $f$ to obtain an acceptance region $\left(\mathrm{c}_{\mathrm{i} 1}, \mathrm{c}_{\mathrm{i} 2}\right)$ of $\mathrm{p}_{\mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k}-1)$.

Then test $H_{0}: p_{i}=p_{0 i}(i=1, \ldots k)$ against $H_{1}: p_{i} \neq p_{0 i}$ for at least one i ; where $\mathrm{p}_{0 \mathrm{i}}$ is chosen such that:

When $\mathrm{r}=1, \mathrm{p}_{0 \mathrm{i}} \approx \mathrm{c}_{\mathrm{i} 2}(\mathrm{~L}, 1) / \mathrm{n}=\mathrm{c}_{\mathrm{i} 2} / \mathrm{n}(\mathrm{i}=1, \ldots \mathrm{k}-1)$, where the approximation is made subject to $\sum \mathrm{p}_{0 \mathrm{i}}=1$. If $\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k})$ is accepted, then $\mathrm{p}_{\text {uiL } 1}=\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k}) . \mathrm{A}$ new set of hypothetical values of $\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k}-1)$ is chosen such that $\mathrm{p}_{0 \mathrm{i}}>\mathrm{p}_{\text {uiL1 }}(\mathrm{i}=1, \ldots \mathrm{k}-1)$ which are rejected when tested. For these rejected $\left.p_{0 i}(i=1, \ldots k)\right)$, set $\mathrm{p}_{\text {uiUl }}=\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k})$.

Otherwise $(r=1)$, if $p_{0 i}(i=1, \ldots k)$ is rejected, then $p_{\text {uiUl }}$ $=p_{0 i}(i=1, \ldots k)$. A new set of hypothetical values of $p_{0 i}(i$ $=1, \ldots \mathrm{k}-1)$ is chosen such that $\mathrm{p}_{0 \mathrm{i}}<\mathrm{p}_{\text {uiUl }}(\mathrm{i}=1, \ldots \mathrm{k}-1)$ which are accepted when tested. For these accepted $p_{0 i}$ (i $=1, \ldots k)$, set $p_{u i L 1}=p_{0 i}(i=1, \ldots k)$.

With $\mathrm{r} \geq 1, \mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k}-1)$ is chosen at the $\mathrm{r}+1^{\text {th }}$ iteration such that $\mathrm{p}_{\text {uiUr }}>\mathrm{p}_{0 \mathrm{i}}>\mathrm{p}_{\text {uiLr }}$ if $\mathrm{p}_{\text {uiUr }}>\mathrm{p}_{\text {uiLr }}$; and otherwise $\mathrm{p}_{0 \mathrm{i}}=\mathrm{p}_{\mathrm{ui}}=\mathrm{p}_{\text {uiUr }}$ if $\mathrm{p}_{\text {uiUr }}=\mathrm{p}_{\text {uiLr }}$, with the iteration stopped.

If $\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k}-1)$ is accepted, then $\mathrm{p}_{u i L(\mathrm{r}+1)}=\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=$ $1, \ldots \mathrm{k}-1)$ and $\mathrm{p}_{\text {uiU }(\mathrm{r}+1)}=\mathrm{p}_{\text {uiUr }}(\mathrm{i}=1, \ldots \mathrm{k}-1)$.

Otherwise, $\mathrm{p}_{\text {uiL }(r+1)}=\mathrm{p}_{\text {uiLr }}(\mathrm{i}=1, \ldots \mathrm{k}-1)$ and $\mathrm{p}_{\text {uiU }(\mathrm{r}+1)}=$ $\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k}-1)$. Therefore $\mathrm{p}_{\mathrm{uiU}(\mathrm{r}+1)}-\mathrm{p}_{\mathrm{uiL}(\mathrm{r}+1)}>0(\mathrm{i}=1$, $\ldots \mathrm{k}-1)$ and is decreased at the $\mathrm{r}+1^{\text {th }}$ iteration. As $\mathrm{r} \rightarrow \infty$, $\mathrm{p}_{\text {uiUr }}-\mathrm{p}_{\text {uiLr }} \rightarrow 0(\mathrm{i}=1, \ldots \mathrm{k}-1)$. But $\mathrm{p}_{\text {uiUr }}-\mathrm{p}_{\text {uiLr }}=\left(\mathrm{p}_{\text {uiUr }}\right.$ $\left.-p_{u i}\right)+\left(p_{u i}-p_{u i L r}\right)$. So $p_{u i U r} \rightarrow p_{u i}$ and $p_{u i L r} \rightarrow p_{u i}$ as $r \rightarrow$ $\infty(\mathrm{i}=1, \ldots \mathrm{k}-1)$ since $\mathrm{p}_{\mathrm{uiUr}} \geq \mathrm{p}_{\mathrm{ui}} \geq \mathrm{p}_{\text {uiLr }}$. A similar result applies to $\mathrm{p}_{\mathrm{li}}(\mathrm{i}=1, \ldots \mathrm{k}-1)$.
$\uparrow$
So $\mathrm{p}_{\mathrm{ui}}$ and $\mathrm{p}_{\mathrm{li}}(\mathrm{i}=1, \ldots \mathrm{k}-1)$ can be estimated to any accuracy, at a given sufficiently large test size $\alpha$. This is possible because the above intervals ( $\mathrm{c}_{\mathrm{i} 1}, \mathrm{c}_{\mathrm{i} 2}$ ) can be computed from the data and the null distribution, as shown by Lemma 2.1 and Algorithm 5.6 of the Appendix.

Example: Consider some of the data of Topp et al. [4]. This is summarized in Table 1. For the above case, $\mathrm{i}=1$ and $p_{1}$ is the probability of an occurrence of diplegia in the sample. Thus $\left(\mathrm{p}_{11}, \mathrm{p}_{\mathrm{u} 1}\right)$ is the interval estimate of $\mathrm{p}_{1}$ with a probability of .976 for the occurrence of diplegia for Preterm 1983-86; so that the Tsakok test of fit was used at a significance level of 1-. 976 (i.e., .024). The small variations in the confidence levels arise out of the non-randomized tests applied to discrete data. Normality is not assumed.

TABLE I. Preterm and Term Diplegia Occurrence

|  | Preterm 1983-80 | Term 1987-90 |
| :--- | :--- | :--- |
| Sample Size | 170 | 171 |
| No (\%) Diplegia | $113(66)$ | $69(40)$ |
| $\left(\mathbf{p}_{\mathbf{1} 1}, \mathbf{p}_{\mathbf{u} 1}\right)$ | $(.58, .70)$ | $(.36, .49)$ |
| Confidence level | .976 | .979 |

## 3. COMPARING THE DISTRIBUTIONS

As indicated by Tsakok [5], the interval estimates of distributions immediately enable comparisons between them to be made. This is also discussed in Tsakok [6]. The technique is similar to that used by Tsakok [7] to solve the Behrens-Fisher problem.

Thus if $F_{1}$ and $F_{2}$ are two distributions from independent populations 1 and 2, the problem is to decide with a test $f_{12}$ between the hypotheses:
$H: F_{1}=F_{2}=F$, say, and $K: F_{1} \neq F_{2}$;
from independent random samples of size $n_{j}$ for each population $\mathrm{j}(\mathrm{j}=1,2)$. With the above method, let $\mathrm{C}_{\mathrm{j}}$ be the set of distributions that are acceptable hypothetical distributions for population j using a Tsakok test of fit $f_{\mathrm{j}}$ at significance level $\alpha_{j}$. Thus $P\left(F \in C_{j} \mid F_{j}=F\right)=1-\alpha_{j}=1-$ $\mathrm{E}\left(f_{\mathrm{j}} \mid \mathrm{F}_{\mathrm{j}}=\mathrm{F}\right)$. Since the samples are independent, $\mathrm{P}((\mathrm{F} \in$ $\left.\left.\mathrm{C}_{1}\right) \bigcap\left(\mathrm{F} \in \mathrm{C}_{2}\right) \mid \mathrm{F}_{1}=\mathrm{F}_{2}=\mathrm{F}\right)=\left(1-\alpha_{1}\right)\left(1-\alpha_{2}\right)$. With $f$ ${ }_{12}=1-\left(1-f_{1}\right)\left(1-f_{2}\right)$, the test size $\alpha$ of H is $\mathrm{E}(f$ $\left.{ }_{12} \mid \mathrm{H}\right)=\mathrm{E}\left(1-\left(1-f_{1}\right)\left(1-f_{2}\right)\right)=\alpha=1-\left(1-\alpha_{1}\right)(1-$ $\alpha_{2}$ ), being the probability that at least one of the events (F $\in C_{j} \mid F_{j}=F$ ) does not occur.

Let $\mathrm{Q}=\mathrm{C}_{1} \bigcap \mathrm{C}_{2}$. If Q is empty, at least one of the events $\left(F \in C_{j} \mid F=F_{j}\right)$ will not occur, leading to:

## Reject H if Q is empty.

When Q is not empty, H may be either accepted or rejected, depending on whether or not the F chosen by the test of fit belongs to Q , showing that the concept of acceptance regions is inadequate. To overcome this inadequacy, the following complementary concept is proposed:

Definition 3.1. With hypothetical distribution $\mathrm{F}_{0}$ fully specified, $\mathrm{P}(\mathrm{Q})=\mathrm{P}\left(\mathrm{F}_{0} \in \mathrm{Q} \mid \mathrm{F}=\mathrm{F}_{0}\right)$.

Theorem 3.2. Using the test $f_{12}=1-\left(1-f_{1}\right)(1-f$ 2) at the test size $\alpha, 0 \leq \mathrm{P}(\mathrm{Q}) \leq 1-\alpha$.

Proof. For $f_{\mathrm{j}}, \mathrm{C}_{\mathrm{j}}$ is of the form $\left(\mathrm{p}_{\mathrm{i}},(\mathrm{i}=1, \ldots \mathrm{k}-1): \mathrm{p}_{\mathrm{i}}\right.$ $\left.\in\left(\mathrm{p}_{\mathrm{lij}}, \mathrm{p}_{\mathrm{uij}}\right), \mathrm{i}=1, \ldots \mathrm{k}-1\right)$, where the classes i are mutually exclusive, and ( $\mathrm{p}_{\mathrm{lij}}, \mathrm{p}_{\mathrm{uij}}$ ) is a real interval for which $\mathrm{p}_{\mathrm{lij}}<\mathrm{pi}<\mathrm{p}_{\mathrm{uij}}$ with probability $1-\alpha_{\mathrm{j}}$. Let $\left(\mathrm{a}_{\mathrm{i}}, \mathrm{b}_{\mathrm{i}}\right)=$ $\bigcap_{j}\left(p_{\text {iij }}, p_{u i j}\right), i=1, \ldots k-1$. Then $Q=\left(p_{i},(i=1, \ldots k-\right.$ 1): $\left.p_{i} \in\left(a_{i}, b_{i}\right), i=1, \ldots k-1\right)$. For a member $F_{0}$ of $C_{j}$ with $\left(\mathrm{c}_{\mathrm{ij} 1}, \mathrm{c}_{\mathrm{ij} 2}\right)$ as the acceptance region for population j ( $\mathrm{i}=$
$1, \ldots . \mathrm{k}-1)$ using $f_{\mathrm{j}}$ at the test size $\alpha_{\mathrm{j}}$, let $\mathrm{A}_{\mathrm{j}}=\left(\left(\mathrm{c}_{\mathrm{ij} 1} / \mathrm{n}_{\mathrm{j}}\right.\right.$, $\mathrm{c}_{\mathrm{ij} 2} / \mathrm{n}_{\mathrm{j}}$ ), $\mathrm{i}=1, \ldots \mathrm{k}-1$ ) for population j using $f_{\mathrm{j}}$ for the hypothesis that $\mathrm{F}_{\mathrm{j}}=\mathrm{F}_{0}$. So event $\left(\mathrm{F}_{0} \in \mathrm{~A}_{\mathrm{j}} \mid \mathrm{F}_{\mathrm{j}}=\mathrm{F}_{0}\right)$ occurs whenever event $\left(f_{\mathrm{j}}=0 \mid \mathrm{F}_{\mathrm{j}}=\mathrm{F}_{0}\right)$ occurs at the test size $\alpha_{\mathrm{j}}$, with $F_{0}$ partitioned into mutually exclusive class probabilities $\mathrm{p}_{0 \mathrm{i}}(\mathrm{i}=1, \ldots \mathrm{k})$ as above, since then $\mathrm{p}_{0 \mathrm{i}} \in$ $\left(\mathrm{c}_{\mathrm{ij} 1} / \mathrm{n}_{\mathrm{j}}, \mathrm{c}_{\mathrm{ij} 2} / \mathrm{n}_{\mathrm{j}}\right)(\mathrm{i}=1, \ldots \mathrm{k}-1)$, with the hypothesis $\left(\mathrm{F}_{\mathrm{j}}=\right.$ $\left.\mathrm{F}_{0}\right)$ accepted. So $\mathrm{P}\left(\mathrm{F}_{0} \in \mathrm{Q} \mid \mathrm{F}=\mathrm{F}_{0}\right)=\mathrm{P}\left(\mathrm{F}_{0} \in \bigcap_{\mathrm{j}} \mathrm{A}_{\mathrm{j}} \mid \mathrm{F}_{1}=\mathrm{F}_{2}\right.$ $\left.=\mathrm{F}_{0}\right)=\mathrm{P}\left(\mathrm{F}_{0} \in \bigcap_{\mathrm{j}} \mathrm{A}_{\mathrm{j}} \mid \mathrm{F}_{1}=\mathrm{F}_{0}\right) \mathrm{P}\left(\mathrm{F}_{0} \in \bigcap_{\mathrm{j}} \mathrm{A}_{\mathrm{j}} \mid \mathrm{F}_{2}=\mathrm{F}_{0}\right)$. Hence $0 \leq \mathrm{P}(\mathrm{Q}) \leq 1-\alpha$. In particular, $\mathrm{P}(\mathrm{Q})=0$ if $\mathrm{Q}=0$.

The above expression for $\mathrm{P}(\mathrm{Q})$ uses the fact that the events $E_{s}=\left(F_{0} \in \bigcap_{j} A_{j} \mid F_{s}=F_{0}\right)$ are independent, for $\mathrm{s}=$ 1,2 . This is true because $\mathrm{E}_{\mathrm{s}}$ is contained in $\mathrm{G}_{\mathrm{s}}$ only, where $\mathrm{G}_{\mathrm{s}}=\left(\mathrm{F}_{0} \in \mathrm{~A}_{\mathrm{s}} \mid \mathrm{F}_{\mathrm{s}}=\mathrm{F}_{0}\right)$, and $\mathrm{G}_{1}, \mathrm{G}_{2}$ are independent by hypothesis. For if $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ were not independent, then when $E_{s}=G_{s}(s=1,2)$, this contradicts the hypothesis of independence of $\mathrm{G}_{1}, \mathrm{G}_{2}$. $\dagger$

The Appendix proves a more general result.
Values of $\mathrm{P}(\mathrm{Q})$ close to its maximum or indicating considerable (at least $95 \%$ ) overlap with at least one of the confidence intervals support the view that H should be accepted but not otherwise, as it suggests that a Type II error would then be made. Thus corrective action can be taken if necessary. $\mathrm{P}(\mathrm{Q})$ is not needed if $\mathrm{Q}=0$ (i.e. Q is empty). The asymptotic properties of $\mathrm{P}(\mathrm{Q})$ have been considered by Tsakok [6].

Since the method is to measure the amount of overlap between confidence intervals for the comparisons, there is no p value, but $\mathrm{P}(\mathrm{Q})$ instead. The method described is now applied to the above data. Hence
$\mathrm{F}_{1}=$ distribution of the incidence of diplegia for Preterm 1983-86
$\mathrm{F}_{2}=$ distribution of the incidence of diplegia for Term 1987-90
$\mathrm{Q}=0$, from Table 1.
Thus H is rejected at .04 ( 1 significant figure) significance level.

The two-sample test using the Tsakok technique has shown that, due to its exact UMPU properties, it is able to detect differences where Topp et al. [4] have failed using chi-squared tests at the .05 significance level; as the latter does not share these characteristics.

This is just one of several significant differences which Topp et al. [4] failed to discover because they relied on the asymptotic approximations of chi-squared tests and marginal totals.

The choice of class probabilities is not unique, but since for given k , the number of classes, each set of possible mutually exclusive pre-specified class probabilities is different from the other, it is not possible
to compare the outcome of the above tests with each other; resulting in no possible contradictions between these above tests. In fact, the different sets of class probabilities complement each other in the data analysis.

## 4. Comparisons with Other Methods

The interval estimates of distributions, up to their class probabilities, are exact and inherit the optimal properties of the Tsakok test of fit with which they were obtained. By comparison, the Kolmogorov single-sample statistic has been shown to be biased (Massey [8]).

The results of Massey [8] also show that the Kolmogorov-Smirnov two-sample test is biased, since it cannot be unbiased for large sample sizes of one population.

Theorem 4.1. If the Tsakok test of fit is used for each $f$ ${ }_{\mathrm{j}}(\mathrm{j}=1,2)$, the test $f_{12}$ for testing $\mathrm{H}: \mathrm{F}_{1}=\mathrm{F}_{2}$ against $\mathrm{K}: \mathrm{F}_{1}$ $\neq \mathrm{F}_{2}$ is UMPU against some two-sided alternatives for which $\mathrm{p}_{\mathrm{ji}} \neq \mathrm{p}_{0 \mathrm{i}}$ for one $\mathrm{j}>0$ and one i only under K ; and unbiased against all alternatives under K .

Proof. If $\mathrm{F}_{1} \neq \mathrm{F}_{2}$ when comparing samples, then $\mathrm{F}_{\mathrm{j}} \neq \mathrm{F}_{0}$ for at least one j for any $\mathrm{F}_{0}(\mathrm{j}=1,2)$. Thus if $\mathrm{p}_{\mathrm{j} i}$ is the probability of an observation falling in class i given $\mathrm{F}_{\mathrm{j}}(\mathrm{j}=$ $0,1,2$ ), it is possible that $\mathrm{p}_{\mathrm{ji}} \neq \mathrm{p}_{0 \mathrm{i}}$ for one $\mathrm{j} \neq 0$ and one i only under K. Hence the optimal properties of the Tsakok test of fit $f_{\mathrm{j}}$ result in a test of H which is UMPU against some two-sided alternatives for which $\mathrm{p}_{\mathrm{ji}} \neq \mathrm{p}_{0 \mathrm{i}}$ for one $\mathrm{j}>0$ and one i only under K ; and unbiased against all alternatives under K. $\uparrow$

This compares with the Wilcoxon test $[9,10]$ or other similar tests based on ordered samples, such as those by Gehan [11], Mantel [12] and Cox [13], which have been shown to be biased against the two-sided alternative (Lehmann [14]). The pre-test by Martinez and Narano [15] does not address this problem of biasedness.

In the chi-squared statistic involving all the k classes, one of the classes k is determined by the other $\mathrm{k}-1$ classes, and so is redundant in that sense. Apart from being approximate and biased (Kendall and Stuart [2, p. 453]), chi-squared tests on contingency tables are conditional upon the marginal totals, unlike the method used here. So the method proposed here gives results that are more generally applicable.

To achieve tests not based on conditional distributions, Suissa and Shuster [16] chose $p_{\text {sup }}=\sup _{\pi \in[0,1]} p(\pi)$, where $\pi$ is the common proportion of 2 independent binomial distributions, whose proportions are being compared. This suffers from the difficulty that the $\pi$ thus chosen may not be that of the distributions under study.

A similar criticism applies to the approach used by Storer and Kim [17], since the maximum likelihood estimate of $\pi$ may not be that of the binomial distributions concerned when comparing their proportions, and is therefore irrelevant.

Berger and Boos [18], in comparing binomial proportions with distributions which are not conditional, maximised the $p$ value by a choice of $\pi$ over a confidence set. It thus suffers from the same criticism that the $\pi$ chosen may not be that of the binomial populations of interest, and so is irrelevant.

Berger and Boos [18] also refer to their computational difficulties. The above numerical example illustrates no computational problems with the method used here.

When comparing samples, Bithell and Stone [19] proposed a Maximum Likelihood Ratio (MLR) statistic for comparing populations. The problem with their method is that the null distribution of their MLR statistic is unknown for small samples.

The Linear Risk Scores (LRS) statistic of Bithell et al. [20] for comparing populations is hard to interpret, apart from having an unknown distribution; as they noted. Consequently Bithell et al. [20] only made qualitative comparisons using LRS and MLR statistics.

By comparison, the method proposed here is exact, and gives clear results; using incidence rates of the populations concerned.

As the principle used for comparing distributions is similar to that used by Tsakok [7] for solving the BehrensFisher problem, other publications on it are relevant. In particular, Matuszewski and Sotres [21] proposed a test for a variation of the Behrens-Fisher problem: They tested $\mathrm{H}: \mu_{1}=\mu_{2}$ of two independent normal populations with means $\mu_{1}$ and $\mu_{2}$ against $\mathrm{K}: \mu_{1}<\mu_{2}$. Let $\left(\mathrm{a}_{\mathrm{j}}, \mathrm{b}_{\mathrm{j}}\right)$ be the $80 \%$ confidence interval for $\mu_{\mathrm{j}}(\mathrm{j}=1,2)$.

The test then rejects H at the nominal .05 significance level if and only if $\mathrm{b}_{1}<\mathrm{a}_{2}$, assuming unknown variances.

This test differs from Tsakok [7] in two respects: Unlike Tsakok [7], it does not test H against the two sided alternative that the means are unequal, which is the standard formulation of the Behrens-Fisher problem found in most texts, such as Kendall and Stuart [2].

Secondly, it rejects H if and only if the confidence intervals do not overlap, with $b_{1}<a_{2}$. This differs from the Tsakok [7] test for the Behrens- Fisher problem, which rejects H if (but not only if) the confidence intervals for the means do not overlap.

Therefore the characteristics of the two tests differ. Matuszewski and Sotres [21] do not claim that their test is exact, and only applies to the .05 nominal significance level. By comparison, the Tsakok [7] test is exact and optimal, at any significance level in $(0,1)$ in the frequentist sense.

The two-sample problem amounts to a problem of deciding whether two groups of data, as specified above, should be classified into the same or different groups. For this problem, Kline [22] made restricted comparisons with numerical examples between the nonparametric Bayesian

Data Reduction Algorithm (BDRA), the Linear Discriminant Analysis and the Quadratic Analysis. He admits that BDRA lacks explanatory power and its theoretical operating characteristics are unclear. He does not claim that the BDRA has theoretical optimal properties, unlike the proposal presented here. Kayano and Dozono [23] use cluster analysis to the classification problem, under the normality assumption. They also make limited numerical investigations into the effectiveness of their approach, with no optimality claims. The normality assumption is here shown to be unnecessary for classification, and the theoretical effectiveness of the present proposal is established with its optimal properties.

These clear advantages of the method proposed here over its competitors make further comparisons unnecessary.

## 5. APPENDIX

Definition 5.1. A' will be said to be contained in event A only in the well-known sense that A' consists of sample points of A only, excluding any sample point that may simultaneously belong to another event B . Thus for the event $(A \cap B), A^{\prime}$ is $\operatorname{not}(A \cap B)$ if events $A$ and $B$ are unequal.

Theorem 5.2. Let A and B be independent events, and A' be contained in A only. Then A' cannot be dependent on $B$, if $P(B)>0$ and $A-A^{\prime}$ is independent of $B$.

Proof. If $A$ and $B$ are independent events, then $P(A \cap$ $B)=P(A) P(B)$. Suppose $A$ contains $A^{\prime}$ only, but $A^{\prime}$ is dependent on $B$. If $A-A$ is empty, then $A=A$, so that a contradiction is established. If it is not empty, A - A must be independent of $B$ by hypothesis. So $P((A-A)$ $\cap \mathrm{B})=\mathrm{P}\left(\mathrm{A}-\mathrm{A}^{\prime}\right) \mathrm{P}(\mathrm{B})$. Thus $\mathrm{P}(\mathrm{A} \cap \mathrm{B})=\mathrm{P}\left(\left(\mathrm{A}^{\prime} \cup(\mathrm{A}\right.\right.$ $\left.\left.\left.-A^{\prime}\right)\right) \cap \mathrm{B}\right)=\mathrm{P}\left(\left(\mathrm{A}^{\prime} \cap \mathrm{B}\right) \bigcup\left(\left(\mathrm{A}-\mathrm{A}^{\prime}\right) \cap \mathrm{B}\right)\right)=\mathrm{P}\left(\mathrm{A}^{\prime}\right.$ $\cap B)+P\left(\left(A-A^{\prime}\right) \cap B\right)=P\left(A^{\prime} \mid B\right) P(B)+P(A-$ $\left.A^{\prime}\right) P(B)$. Since $P(A \cap B)=P(A) P(B)$, then $P(A \cap B)=$ $\mathrm{P}\left(\mathrm{A}^{\prime} \cup\left(\mathrm{A}-\mathrm{A}^{\prime}\right)\right) \mathrm{P}(\mathrm{B})=\left(\mathrm{P}\left(\mathrm{A}^{\prime}\right)+\mathrm{P}\left(\mathrm{A}-\mathrm{A}^{\prime}\right)\right) \mathrm{P}(\mathrm{B})=\mathrm{P}$ $\left(A^{\prime}\right) P(B)+P\left(A-A^{\prime}\right) P(B)$. So $P\left(A^{\prime}\right)=P\left(A^{\prime} \mid B\right)$, and $A^{\prime}$ is independent of B (Feller [24], p125); contrary to the supposition that A is dependent on B .

Using Feller's [24, p.128] definition of mutual independence, a similar argument readily establishes:

Theorem 5.3. Let $\mathrm{A}_{1}, \ldots \mathrm{~A}_{\mathrm{n}}$ be mutually independent events, for which $\mathrm{P}\left(\mathrm{A}_{\mathrm{i}}\right)>0(\mathrm{i}=1, \ldots \mathrm{n})$, and event $\mathrm{A}_{\mathrm{i}}^{\prime}$ be contained in $\mathrm{A}_{\mathrm{i}}$ only. Then event $\mathrm{A}_{\mathrm{i}}^{\prime}$ cannot be dependent on $\bigcap(j: j \neq i, j=1, \ldots n) A_{j}$; when $A_{i}-A_{i}^{\prime}$ is mutually independent with $\left(\mathrm{A}_{\mathrm{j}}\right)_{(\mathrm{i}: \mathrm{j} ; \mathrm{i})}$.

If the Tsakok test of fit $f$ is used, the following considerations should assist in its use.

Definition 5.4. A scan of class $i$ is the process of alternately determining $\mathrm{n}_{\mathrm{i}}=\mathrm{np}_{0 \mathrm{i}}-\mathrm{d}_{\mathrm{i} 1}$ and $\mathrm{n}_{\mathrm{i}}=\mathrm{np}_{0 \mathrm{i}}+\mathrm{d}_{\mathrm{i} 2}$ given $\mathrm{n}_{\mathrm{j}} \forall \mathrm{j} \neq \mathrm{i}, \mathrm{k}$, as integers $\mathrm{d}_{\mathrm{il}}$ and $\mathrm{di}_{2}$ are each
increased from 0 to at most z in that order, for some integer $\mathrm{z} . \mathrm{z}$ is chosen to satisfy the significance level of the non-randomised test $f$ and the unbiasedness condition for class i as closely as possible. $z$ must minimise $\mid \mathrm{E}\left(\mathrm{n}_{\mathrm{i}}\right.$ $\left.\mathrm{np}_{0 \mathrm{i}}\right) f\left(\mathrm{H}_{0}\right) \mid$.

Definition 5.5. A multi scan of class $\mathrm{i}>1$ is a scan of class $i$ where after each ordered increase of $d_{i 1}$ or $d_{i 2}$, a scan of classes 1 to $\mathrm{i}-1$ are made in that order, with each ordered change in $\mathrm{d}_{\mathrm{sj}}$ during the scan of class $\mathrm{s}>1$ similarly resulting in a scan of classes 1 to $s-1$ in that order for any $\mathrm{s}<\mathrm{i}, \mathrm{j}=1,2$.

Algorithm 5.6. With classes i ordered from 1 to $\mathrm{k}-1$, a scan of class $i=1$ is made, followed by multi scans of classes 2 to $k-1$ in that order. Then for each value of $n_{2}$ formed during the multi scan of class $i=2$, there will be a pair ( $\mathrm{n}_{1}, \mathrm{n}_{2}$ ) with each of the values of $\mathrm{n}_{1}$ formed during the scan of class $i=1$. Similarly, each value of $n_{3}$ formed during the multi scan of class $i=3$ will form a triple ( $n_{1}$, $\mathrm{n}_{2}, \mathrm{n}_{3}$ ) with each of the pairs ( $\mathrm{n}_{1}, \mathrm{n}_{2}$ ) formed during the multi scan of class $i=2$. Thus by induction hypotheses the multi scan of class $i=k-1$ will create a set $S$ of $k-1$ tuples ( $\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}-1}$ ) with all the values of $\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}-1}$ formed during the multi scan. The interval of values for each $n_{i}(i=1, \ldots k-1)$ thus formed are $\left(c_{i 1}, c_{i 2}\right)$ since these satisfy the unbiasedness condition by construction, within the limits of non-randomised tests. Moreover, since $f=0$ exactly when $c_{i 1}<n_{i}<c_{i 2}(i=1, . . . k-1)$ for the nonrandomised case, $\alpha \geq 1-\sum_{\mathrm{s}} \mathrm{P}\left(\mathrm{n}_{1}, \mathrm{n}_{2} \ldots \mathrm{n}_{\mathrm{k}}\right)$, where the summation is over all the elements $\left(\mathrm{n}_{1}, \mathrm{n}_{2} \ldots \mathrm{n}_{\mathrm{k}}\right)$ of set S , and $\mathrm{P}\left(\mathrm{n}_{1}, \mathrm{n}_{2} \ldots \mathrm{n}_{\mathrm{k}}\right)$ is the multinomial distribution. Integer z is maximised to satisfy the above inequality for $\alpha$ for the non-randomised test $f$; and is decreased otherwise if this inequality is not satisfied.
