# A linear weighted estimator for estimating population total or mean of the study variable 

Mariam Al Mannai and Satish K. Agarwal<br>Department of Mathematics, College of Science, University of Bahrain, Kingdom of Bahrain<br>e-mail: malmannai@sci.uob.bh

#### Abstract

In this paper we have extended the expressions of Bias and Mean square error of the estimators of Agarwal and Al-Mannai (2008) from first order of approximation to the second order of approximation. This helps further to the problem of reducing sampling error in sample surveys, by using the information on auxiliary variables. The usefulness of the estimators is demonstrated with the help of examples taken from the literature.

## 1. INTRODUCTION

To reduce the cost of the sample surveys, the statisticians prefer to estimate the parameters of several characteristics simultaneously. The sampling methodology depends upon the nature of the population and availability of the information and resources. If the information on auxiliary variable highly positively correlated with prime characteristics of interest is available, then the primary units are selected with probability proportional to size (pps) with replacement or without replacement. Selection of primaries with pps of an auxiliary variable, may improve the efficiency of the estimate of population mean/total [Agarwal et al (1978), Chaudhuri and Vos (1988)]. For those characteristics of interest having low or very low correlation with size measure, Rao (1966) introduced certain biased alternative estimators.

In the last four decades several linear weighted estimators are suggested for estimating population mean/total [see Singh (1967), Murthy (1967), Agarwal and Kumar (1980), Amahia et al (1989), Agarwal et al (2003)]. Recently, Agarwal and Al Mannai (2008) has made an attempt to show the importance of linear weighted estimators under ppswr sampling over the alternative estimator and also over the conventional estimators through an empirical study for a wide variety of populations available in the literature. We have extended the expressions of Bias and Mean square error of the estimators of Agarwal and Al-Mannai (2008) from first order of approximation to the second order of approximation. This helps further to the problem of reducing sampling error of the estimators, by using the information on auxiliary variables. The usefulness of the estimators is demonstrated with the help of examples. For the sake of clarity and the empirical studies, we have restricted our study when the information is available on two auxiliary variables

## 2. STATEMENT OF THE PROBLEM

Consider a finite population $U$ of size $N$ identifiable, distinct units $u_{1}, u_{2}, u_{i}, \ldots \ldots . . . u_{N}$, It is assumed that study variables $y$ are defined on $U$. The information is available on two auxiliary variables $\mathrm{x}_{1}$ for each unit of the population while the only information required on $\mathrm{x}_{2}$ is the population
mean $\bar{X}_{2}$. The selection probabilities based on $\mathrm{x}_{1}$, are $\mathrm{p}_{1 \mathrm{i}}\left(=\mathrm{x}_{1 i} / \mathrm{X}_{1} ; \mathrm{X}_{1}=\sum_{i=1}^{N} x_{1 i}\right) ; \mathrm{i}=1,2, \ldots \mathrm{~N}$. The problem is to estimate the population mean/total of study variables y's with the reduced sampling error under the situations:
(i) When y has high linear relationship with $\mathrm{x}_{2}$.
(ii) When y has linear negative relationship with $\mathrm{x}_{2}$.

## 3. LINEAR WEIGHTED ESTIMATOR WHEN STUDY VARIABLE y AND $x_{2}$ ARE LINEARLY RELATED.

Let,

$$
\begin{aligned}
& \mathrm{u}_{\mathrm{i}}=\frac{y_{i}}{N p_{1 i}} ; \mathrm{v}_{\mathrm{i}}=\frac{x_{2 i}}{N p_{1 i}} ; \\
& \bar{u}=n^{-1} \sum_{i=1}^{n} u_{i}=\bar{y}_{p p s} ; \bar{v}=n^{-1} \sum_{i=1}^{n} v_{i}=\bar{x}_{2 p p s} \\
& \mathrm{C}_{\mathrm{lm}}=\frac{\sum_{i} p_{1 i}\left(v_{i}-\bar{X}_{2}\right)^{l}\left(u_{i}-\bar{Y}\right)^{m}}{\bar{Y}^{m} \bar{X}_{2}^{l}} ; 1, \mathrm{~m}=0,1,2, \ldots \\
& \mathrm{~V}\left(\bar{y}_{p p s}\right)=\sigma_{u}^{2}=\frac{1}{n} \sum_{i=1}^{N} p_{1 i}\left(u_{i}-\bar{Y}\right)^{2}=\frac{C_{02} \bar{Y}^{2}}{n} \\
& \sigma_{v}^{2}=\sum_{i=1}^{N} p_{1 i}\left(v_{i}-\bar{X}_{2}\right)^{2}=\frac{C_{20} \bar{X}_{2}^{2}}{n} \\
& \bar{y}_{R}=\frac{\bar{u}}{\bar{v}} \bar{X}_{2} ; \bar{y}_{p}=\frac{\bar{u} \bar{v}}{\bar{X}_{2}} ; \\
& \rho_{u v}=\sum_{i=1}^{N} \frac{p_{1 i}\left(u_{i}-\bar{Y}\right)\left(v_{i}-\bar{X}_{2}\right)}{\sigma_{u} \sigma_{v}}=\frac{C_{11}}{\sqrt{C_{02} C_{20}}}
\end{aligned}
$$

### 3.1 WHEN THE STUDY VARIABLE Y AND $X_{2}$ ARE LINEARLY BUT NEGATIVELY CORRELATED

The proposed estimator $\bar{y}_{1}$ of the population mean $\bar{Y}$ is a linear weighted estimator:

$$
\begin{equation*}
\bar{y}_{1}=w \bar{y}_{p}+(1-w) \bar{y}_{p p s} \tag{1}
\end{equation*}
$$

where w is the weight to be determined.
The bias and mean squared error of $\bar{y}_{1}$ are respectively

$$
\begin{equation*}
B\left(\bar{y}_{1}\right)=w B\left(\bar{y}_{p}\right) \tag{2}
\end{equation*}
$$

and

$$
\begin{equation*}
M\left(\bar{y}_{1}\right)=w^{2} M\left(\bar{y}_{p}\right)+(1-w)^{2} V\left(\bar{y}_{p p s}\right)+2 w(1-w) \operatorname{Cov}\left(\bar{y}_{p}, \bar{y}_{p p s}\right) \tag{3}
\end{equation*}
$$

The value of $w$ which minimizes eqn (3) is

$$
\begin{equation*}
w_{\mathrm{opt}}=\frac{V\left(\bar{y}_{p p s}\right)-\operatorname{Cov}\left(\bar{y}_{p}, \bar{y}_{p p s}\right)}{M\left(\bar{y}_{p}\right)+V\left(\bar{y}_{p p s}\right)-2 \operatorname{Cov}\left(\bar{y}_{p}, \bar{y}_{p p s}\right)} \tag{4}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{M}\left(\bar{y}_{1}\right)_{\min }=\frac{V\left(\bar{y}_{p p s}\right) M\left(\bar{y}_{p}\right)-\operatorname{Cov}^{2}\left(\bar{y}_{p}, \bar{y}_{p p s}\right)}{M\left(\bar{y}_{p}\right)+V\left(\bar{y}_{p p s}\right)-2 \operatorname{Cov}\left(\bar{y}_{p}, \bar{y}_{p p s}\right)} \tag{5}
\end{equation*}
$$

In order to find the bias and mean square error to the second degree of approximation, we define $\delta_{\bar{u}}=\frac{\bar{u}-\bar{Y}}{\bar{Y}} ; \delta_{\bar{v}}=\frac{\bar{v}-\bar{X}_{2}}{\bar{X}_{2}}$, so that $\mathrm{E}\left(\delta_{\bar{u}}\right)=\mathrm{E}\left(\delta_{\bar{v}}\right)=0$.
$B_{2}\left(\bar{y}_{p}\right)=\left(\frac{N-n}{N-1}\right)\left(C_{11} \bar{Y} / n\right)$

$$
\begin{gather*}
M_{2}\left(\bar{y}_{p}\right)=\left(\frac{N-n}{N-1}\right)\left[\left(C_{02}+C_{20}+2 C_{11}\right)+\frac{2(N-2 n)}{n(N-2)}\left(C_{12}+C_{21}\right)+\right.  \tag{6}\\
\left.\frac{3\left(N^{2}+N-6 n N+6 n^{2}\right)}{n^{2}(N-2)(N-3)} C_{22}\right]\left(\bar{Y}^{2} / n\right) \tag{7}
\end{gather*}
$$

$\operatorname{Cov}_{2}\left(\bar{y}_{p}, \bar{y}_{p p s}\right)=\left(\frac{N-n}{N-1}\right)\left[\left(C_{02}+C_{11}\right)+\frac{2(N-2 n)}{n(N-2)}\left(C_{12}\right)\right]\left(\bar{Y}^{2} / n\right)$
On substituting eqns (7) and (8) in eqn (4), and then in eqns (2) and (3) we get bias $B_{2}\left(\bar{y}_{1}\right)$ and MSE $M_{2}\left(\bar{y}_{1}\right)$ up to second degree of approximation. When the population size is sufficiently large, then the expression derived under second degree of approximation doesn't contribute much and can be ignored. Then we consider only the terms of first degree of approximation and the above eqn (7) and eqn (8) reduce to

$$
\begin{align*}
& M_{1}\left(\bar{y}_{p}\right) \cong n^{-1} \bar{Y}^{2}\left(C_{02}+C_{20}+2 C_{11}\right)  \tag{9}\\
& \operatorname{Cov}_{1}\left(\bar{y}_{p}, \bar{y}_{p p s}\right) \cong\left[\left(C_{02}+C_{11}\right)\right]\left(\bar{Y}^{2} / n\right)  \tag{10}\\
& w_{1 \text { opt }} \cong-\left(\frac{C_{11}}{C_{20}}\right) \tag{11}
\end{align*}
$$

To the first degree of approximations, the least bias and mean squared error of $\bar{y}_{1}$ are respectively

$$
\begin{align*}
& B_{1}\left(\bar{y}_{1}\right) \cong-\left(C_{11}^{2} / C_{20}\right)(\bar{Y} / n)  \tag{12}\\
& M_{1}\left(\bar{y}_{1}\right) \cong\left[C_{02}-\left(C_{11}^{2} / C_{20}\right)\right]\left(\bar{Y}^{2} / n\right) \tag{13}
\end{align*}
$$

and

### 1.2 WHEN THE STUDY VARIABLES $Y$ AND $X_{2}$ ARE LINEARLY AND POSITIVELY CORRELATED.

Agarwal and Kumar (1980) defined the linear weighted estimator as follows:

$$
\begin{equation*}
\bar{y}_{0}=k \bar{y}_{R}+(1-k) \bar{y}_{p p s} \tag{14}
\end{equation*}
$$

The bias and MSE of $\bar{y}_{0}$ are

$$
\begin{align*}
& B\left(\bar{y}_{0}\right)=k B\left(\bar{y}_{R}\right)  \tag{15}\\
& M\left(\bar{y}_{0}\right)=k^{2} M\left(\bar{y}_{R}\right)+(1-k)^{2} V\left(\bar{y}_{p p s}\right)+2 k(1-k) \operatorname{Cov}\left(\bar{y}_{R}, \bar{y}_{p p s}\right) \tag{16}
\end{align*}
$$

The value of $k$ which minimizes $M\left(\bar{y}_{0}\right)$ is

$$
\begin{equation*}
k_{\mathrm{opt}}=\frac{V\left(\bar{y}_{p p s}\right)-\operatorname{Cov}\left(\bar{y}_{R}, \bar{y}_{p p s}\right)}{M\left(\bar{y}_{R}\right)+V\left(\bar{y}_{p p s}\right)-2 \operatorname{Cov}\left(\bar{y}_{R}, \bar{y}_{p p s}\right)} \tag{17}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{M}\left(\bar{y}_{0}\right)_{\min }=\frac{V\left(\bar{y}_{p p s}\right) M\left(\bar{y}_{R}\right)-\operatorname{Cov}^{2}\left(\bar{y}_{R}, \bar{y}_{p p s}\right)}{M\left(\bar{y}_{R}\right)+V\left(\bar{y}_{p p s}\right)-2 \operatorname{Cov}\left(\bar{y}_{R}, \bar{y}_{p p s}\right)} \tag{18}
\end{equation*}
$$

The bias and mean square error to the second degree of approximation are:

$$
\begin{align*}
& B_{2}\left(\bar{y}_{R}\right) \cong \frac{N-n}{N-1}\left[\left(C_{20}-C_{11}\right)+\frac{2(N-2 n)}{n(N-2)}\left(C_{21}-C_{30}\right)+\frac{3\left(N^{2}+N-6 n N+6 n^{2}\right)}{n^{2}(N-2)(N-3)}\right. \\
& \left.\quad\left(C_{40}-C_{31}\right)+\frac{3 N(N-n-1)(n-1)}{n^{2}(N-2)(N-3)}\left(C_{20}^{2}-C_{20} C_{11}\right)\right](\bar{Y} / n)  \tag{19}\\
& M_{2}\left(\bar{y}_{R}\right) \cong \frac{N-n}{N-1}\left[\left(C_{20}+C_{02}-2 C_{11}\right)+\frac{2(N-2 n)}{n(N-2)}\left(2 C_{21}-C_{12}-C_{30}\right)+\right. \\
& \quad \frac{3\left(N^{2}+N-6 n N+6 n^{2}\right)}{n^{2}(N-2)(N-3)}\left(C_{40}-2 C_{31}-C_{22}\right)+ \\
& \left.\quad \frac{3 N(N-n-1)(n-1)}{n^{2}(N-2)(N-3)}\left(3 C_{20}^{2}-6 C_{20} C_{11}+C_{20} C_{02}+2 C_{11}^{2}\right)\right]\left(\bar{Y}^{2} / n\right) \tag{20}
\end{align*}
$$

and

$$
\begin{array}{r}
\operatorname{Cov}_{2}\left(\bar{y}_{R}, \bar{y}_{p p s}\right) \cong \frac{N-n}{N-1}\left[\left(C_{02}-C_{11}\right)+\frac{2(N-2 n)}{n(N-2)}\left(C_{21}-C_{12}\right)+\frac{3\left(N^{2}+N-6 n N+6 n^{2}\right)}{n^{2}(N-2)(N-3)}\right. \\
\left.\left(C_{22}-C_{31}\right)\right]\left(\bar{Y}^{2} / n\right) \tag{21}
\end{array}
$$

On substituting eqns (20) and (21) in eqn (17), and then in eqns (15) and (16) we get bias $B_{2}\left(\bar{y}_{0}\right)$ and MSE $M_{2}\left(\bar{y}_{0}\right)$ up to second degree of approximation.
The bias and MSE to the first degree of approximations are:

$$
\begin{align*}
& B_{1}\left(\bar{y}_{0}\right) \cong \frac{N-n}{N-1}\left(C_{20}-C_{11}\right)(\bar{Y} / n)  \tag{18}\\
& M_{1}\left(\bar{y}_{0}\right) \cong \frac{N-n}{N-1}\left(C_{20}+C_{02}-2 C_{11}\right)\left(\bar{Y}^{2} / n\right) \tag{19}
\end{align*}
$$

and
$\operatorname{Cov}_{1}\left(\bar{y}_{R}, \bar{y}_{p p s}\right) \cong \frac{N-n}{N-1}\left(C_{02}-C_{11}\right)\left(\bar{Y}^{2} / n\right)$
The value of $k$ which minimizes the $M\left(\bar{y}_{0}\right)$ to the first degree of approximation is

$$
\begin{equation*}
k_{\text {1opt }}=\frac{C_{11}}{C_{20}} \tag{21}
\end{equation*}
$$

The bias and mean square error of $\bar{y}_{0}$ for $k_{\text {opt }}$, to the first degree of

$$
\begin{align*}
& B_{1}\left(\bar{y}_{0}\right)=n^{-1}\left[C_{11}-C_{11}^{2} / C_{20}\right](\bar{Y} / n)  \tag{22}\\
& M_{1}\left(\bar{y}_{0}\right)=\left[C_{02}-C_{11}^{2} / C_{20}\right]\left(\bar{Y}^{2} / n\right)
\end{align*}
$$

## 2. EMPIRICAL STUDY

To study the relative efficiency and the relative bias of linear weighted estimators over conventional estimator/s under probability proportional to size with replacement (ppswr) sampling we have considered a wide variety of populations that cover most of the practical situations we come across in real life surveys. These populations are taken from the available literature [ Freund and Perles (1999), Hines and Montgomery (1990), Mendenhall et. al (2003), Milton and Arnold (2003), Neter et al (1985) and Ott (1984)].

## Description of populations

Table- 1 and 2 give the characteristics of the populations such as population size N , coefficients of variation of the study variable (y), the auxiliary variables $x_{1}$ and $x_{2}$, the correlation coefficients between ( $y, x_{1}$ ) and ( $y, x_{2}$ ). In table -1 , the population size varies from 16 to 65 , the coefficient of variation of $y$ from $10.25 \%$ to $86.46 \%$, the coefficient of variation of $x_{1}$ from $5.66 \%$ to $73.37 \%$, the coefficient of variation of $x_{2}$ from $3.02 \%$ to $91.02 \%$. The correlation coefficient between ( $y$, $\mathrm{x}_{1}$ ) varies from 0.51 to 0.97 , while the correlation coefficient between ( $\mathrm{y}, \mathrm{x}_{2}$ ) varies from 0.34 to 0.94 . The above described populations thus represent a variety of situations and we further divide these into three categories. The category (i) $\rho_{y x_{2}}$ between 0.3 but $<0.5$; category (ii) $0.5<\rho_{y x_{2}}<$ 0.8 , and category (iii) $\rho_{y x_{2}}>0.8$.

In the table -2 the population size varies from 19 to 50 , the coefficient of variation of $y$ from $13.23 \%$ to $64.88 \%$, the coefficient of variation of $x_{1}$ from $8.74 \%$ to $29.16 \%$, the coefficient of variation of $x_{2}$ from $8.38 \%$ to $42.01 \%$. The correlation coefficient between ( $\mathrm{y}, \mathrm{x}_{1}$ ) varies from 0.44 to 0.98 , while the correlation coefficient between ( $\mathrm{y}, \mathrm{x}_{2}$ ) varies from -0.83 to -0.40 .

Table -3 gives the relative gain in efficiency of the estimator $\bar{y}_{0}$ using second order of
approximation over first order of approximation, and also over $\bar{y}_{R}$ and the reduction in bias of $\bar{y}_{0}$ [ $B_{2}\left(\bar{y}_{0}\right)$ ] over $B_{1}\left(\bar{y}_{0}\right)$ and $B_{2}\left(\bar{y}_{R}\right)$. It can be noted that the gain of using second order of approximation over first order of approximation varies from $10 \%$ to $102 \%$. For more than $75 \%$ of the populations, this gain is more than $30 \%$. Similarly, the relative gain in efficiency of the estimator $\bar{y}_{0}$ using second order ofapprox. over $\bar{y}_{R}$ (using second degree of approx.) varies from $15 \%$ to $580 \%$. The reduction in $B_{2}\left(\bar{y}_{0}\right)$ is also very significant.

Table -4 gives the relative gain in efficiency of the estimator $\bar{y}_{1}$ using second order of approximation over $\bar{y}_{1}$ first order of approximation, and also over $\bar{y}_{P}$ [using second order of approximation] and the gain in relative biases of $\bar{y}_{1}$. It can be noted that the gain of using second order of approximation over first order of approximation varies from $47 \%$ to $155 \%$. Similarly, the relative gain in efficiency of the estimator $\bar{y}_{1}$ using second order of approximation over $\bar{y}_{P}$ (using second degree of approx.) is enormous. There is considerable reduction in biases also.

Table-1 Characteristics of the populations when $\rho_{y x_{2}}>0$
